**Abridged Life Tables by Sex, Race, and Hispanic Ethnicity;
US Population 1989-1991**

Abdelhani Guend

Karen C. Swallen

CDE Working Paper No. 2002-03

Notes on Data and Method

I. DATA

Deaths: Three-year average (1989-1991) of vital statistics deaths, tabulated as needed by Age, Sex, Race, and Hispanic ethnicity. The counts of deaths with age unknown were distributed among age groups according to the weight of each age group within the total deaths, separately for males and females.

Population: Census count of population extracted from PUMS 1% census file 1990

Tables Including Data by Hispanic Ethnicity: The states of Oklahoma, Louisiana, and New Hampshire were filtered out of the data used for the computation of the life tables by Hispanic ethnicity because Hispanic ethnicity was not reported for the deaths of residents in these three states for the years of interest.

Adjustment for Misclassification of Deaths of Hispanic Ethnicity: Data from National Mortality Follow Back Survey (NMFS) were used as gold standard to estimate the rates of adjustment for ages 15 and over, and published rates for ages lower than 15 years. See (Swallen and Guend, forthcoming) for the detailed procedure of adjustment.

II. METHOD

$${}_nM_x = {}_nD_x / {}_nP_x$$

Where ${}_nM_x$ is the death rate, ${}_nD_x$ is a 3-year average count of deaths of age x to $x+n$, and ${}_nP_x$ is the census count of persons of age x to $x+n$.

$${}_nq_x = {}_nM_x / (1 + (1 - {}_na_x) {}_nM_x)$$

Where ${}_nq_x$ is the probability of death between age x and $x+n$, ${}_na_x$ is a coefficient of repartition of deaths within the age group $x, x+n$. ${}_na_x=2.5$ for 5-year age groups and is different from 2.5 for single year and 4-year age groups.

$$l_{x+n} = l_x (1 - {}_nq_x)$$

Where l_x are survivors at age x , and ${}_np_x$ is the function of survival, with ${}_np_x = l_x / l_{x+n}$.

$${}_nL_x = 5/2 (l_x + l_{x+n}) \text{ for } n=5$$

${}_nL_x$ is the number of person-years, or stationary population associated with the life table.

$$T_x = \sum_{x=w}^x {}_nL_x$$

Where x is the upper limit age of the life table. e_x is life expectancy at age x .

$$e_x = T_x / l_x$$
