Notes on Data and Method

I. DATA

Deaths: Three-year state's average (1989-1991) of vital statistics deaths, tabulated by age and sex. The counts of deaths with age unknown were distributed among age groups according to the weight of each age group within the total deaths, separately for males and females.

Population: Census count of state's population extracted from PUMS 5% census file 1990

Disability data: The counts of persons sixteen years and older were extracted from PUMS 5% census file and tabulated by age, sex, and disability status. Disability is defined based on the responses to four questions about disability. Questions 18 and 19 on the 1990 census long form questionnaire addressed four types of physical, mental, or other health condition that has lasted 6 or more months.

18a. Limits the kind or amount of work the person can do at a job.

18b. prevents the person from working at a job.

19a. having difficulty going outside the home alone, for example, to shop or visit a doctor's office.

19b. Having difficulty taking care of one's personal needs, such as bathing, dressing, or getting around inside the house.

A yes response to any of the four questions includes the respondent into the disabled status for the purpose of this study.

II. METHOD

$${}_nM_x = {}_nD_x / {}_nP_x$$

Where ${}_nM_x$ is the death rate, ${}_nD_x$ is a 3-year average count of deaths of age x to $x+n$, and ${}_nP_x$ is the census count of persons of age x to $x+n$.

$${}_nq_x = {}_nM_x / (1 + (1 - {}_na_x) {}_nM_x)$$

Where ${}_nq_x$ is the probability of death between age x and $x+n$, ${}_na_x$ is a coefficient of repartition of deaths within the age group $x, x+n$. ${}_na_x = 2.5$ for 5-year age groups and is different from 2.5 for single year and 4-year age groups.

$$l_{x+n} = l_x (1 - {}_nq_x)$$

Where l_x are survivors at age x , and ${}_np_x$ is the function of survival, with ${}_np_x = l_x / l_{x+n}$.

$${}_nL_x = 5/2 (l_x + l_{x+n}) \text{ for } n=5$$

${}_nL_x$ is the number of person-years, or stationary population associated with the life table.

$$T_x = \sum_{x=w}^x nL_x$$

Where x is the upper limit age of the life table. e_x is life expectancy at age x .

$$e_x = T_x / l_x$$

$${}_nW_x = {}_nD'_x / {}_nP_x$$

Where ${}_nD'_x$ is the count of persons with disability in the age group $x, x+n$; ${}_nW_x$ is the prevalence rate of disability for age group $x, x+n$ ($x=15, 20, \dots, 90$ years and over). $(1 - {}_nW_x)$ is multiplied by ${}_nL_x$, the result is person-years free of disability (${}_nL_x^h$).

$${}_nL_x^h = {}_nL_x \cdot (1 - {}_nW_x)$$

$$T_x^h = \sum_{x=w}^x {}_nL_x^h$$

Disability Adjusted Life Expectancy (DALE), is obtained in the usual way.

$$DALE = T_x^h / l_x$$
